Strawberry Care Guide:

PLANTING - plant in sunny location, as strawberries dislike shady areas and will not perform to their full potential

The Pollination is essential for fruit production, this is taken care of by pollinating insect.

If you decide to grow Strawberries in a greenhouse just run your hand over the open flowers, and the pollinating job is done.

WATERING – Strawberries are thirsty plants, make sure they have enough water supply specially during hot weather, try to avoid spraying water on fruits to avoid blemishes and rot settling in. Water at the root of the plant

FEEDING – Strawberries require high potash feed like Tomato fertiliser in order to produce good crops of berries. This needs to be applied regularly once the fruit starts growing.

Alternatively slow-release fertiliser can be applied at the start of the season for trouble-free contact supply of feed.

HARVESTING – pick the strawberries when they are red but still firm, by pulling on stalk, to avoid bruising. Avoid picking in hot weather, the strawberry skin turns soft and mushy when touched.

COVERING – Birds (specially Blackbirds) are great at finding and eating strawberries as soon as they turned red. If you do not mind sharing, no need to do anything. However, if sharing gets out of hand there is an option of fruit protecting netting which needs to be installed correctly to prevent any damage to the wildlife.
